

AN IOS APP CLIP FOR CRYPTO PAYMENTS

The Universal *deposit* Portal.

Scan, pay, done. A native iOS App Clip that turns crypto receiving into the easiest transaction on the internet — no app install, no browser, no URL.

01

SECTION ONE

Crypto payments fail at the simplest step.

Two people trying to move money have to negotiate chains, wallets, and assets before anything happens. The friction kills the transaction.

What actually happens:

- Sender scans receiver's QR code with their wallet
- Wallet only supports certain chains — fails silently or errors out
- Back and forth: *"What chain are you on? I only have USDC on Polygon. I need it on Base."*
- Sender doesn't have the right asset — transaction abandoned
- Worst case: sender doesn't have crypto at all — no path forward

Most people who want to pay someone in crypto give up before they finish.

02

SECTION TWO

The QR code shouldn't open a URL. It should launch an App Clip.

URLs feel foreign. Browsers feel insecure. Users hesitate. App Clips are **native iOS experiences** that load in under a second, run with full system access, and require zero install.

WHY NOT A URL

It feels foreign.

- Opens Safari — adds a browser shell
- No native Apple Pay sheet
- Wallet deep-links break inconsistently
- Users hesitate on unknown domains
- Slow first paint, layout jumps

WHY APP CLIP

It feels native — because it is.

- System-rendered card slides up from QR
- Native Apple Pay sheet works instantly
- Deep-links into installed wallets cleanly
- Apple-verified developer = trust by default
- Under 10MB, loads in <1 second

The new flow.

APP CLIP FLOW

**The receiver specifies what they want. The sender picks how to pay.**

Everything else happens in the background — chain bridging, token swap, fiat conversion. The receiver always lands with the exact asset they asked for.

03

SECTION THREE

The full flow.

Eight screens, end-to-end. From the moment a partner app shows a QR code, to the moment funds land in the user's wallet. No app install. No browser. No URL.

The flow, continued.

Zero install. Zero browser. Pure native iOS.

The entire transaction — scan to confirmation — happens inside an Apple-verified, system-rendered card. The user never sees a URL or downloads anything. The optional full app is offered after the payment succeeds, never before.

04

SECTION FOUR

What it actually feels like.

Two zoomed views — the moment of scan, and the moment of choice. This is the entire product experience for 90% of users.

THE SCAN

CARD SLIDES UP IN <1 SECOND. NO DOWNLOAD.
NO BROWSER.

THE CHOICE

SIX RAILS, ONE OUTCOME. SENDER PICKS;
PORTAL CONVERTS.

05

SECTION FIVE

The QR is a teacher.

People see a QR and assume "wallet address — only my wallet app can scan this." We have to teach the eye *before* the scan. Every QR is wrapped in a card that telegraphs three things instantly: **scan with camera**, **pay with anything**, **opens natively**.

LARGE · IN-STORE

MEDIUM · RECEIPT

SMALL · WEB EMBED

Light variant — for receipts, packaging, and print contexts.

LARGE · LIGHT

ANATOMY

Every element is a signal.

- **Card framing** — looks like a payment instrument, not a crypto address.
- **"Scan to pay"** — explicit verb removes wallet-app assumption.
- **Payment halo** — six logos pre-answer "what works?"
- **Brand mark center** — orange "D" badge replaces standard QR error-correction. Distinctive, trustworthy.
- **"Open camera" footnote** — overrides muscle memory of opening a wallet app.
- **Amount shown** — confirms this is a payment, not a contact card.

06

SECTION SIX

Every wallet's Receive tab is broken.

Today, "Receive" means one thing: *here's a QR with my wallet address, please figure out which chain to send it on.* That conflates two completely different jobs into one bad UI. **Receive should fork on intent** — Self, Request, or Tip — and the Request flow is the crypto Venmo we've been missing.

01 / RECEIVE

The fork on intent

02 / REQUEST

Set what you want

03 / SHARE

Send the QR or link

04 / FRIEND RECEIVES

The link in chat

07

SECTION SEVEN

Six rails. One outcome.

RAIL	WHAT IT DOES	BEST FOR
Apple Pay	Native iOS sheet — fiat → crypto via on-ramp in background	Mainstream, fastest UX
Connect Wallet	Deep-link to Phantom, MetaMask, Trust, OKX, Rabby	Crypto-native users
Centralized Exchange	Coinbase, Binance, Kraken API — send from exchange	Funds-on-exchange majority
Any Token, Any Chain	Wallet holds any token anywhere — background swap delivers target	Scattered crypto holdings
Venmo / PayPal	Fiat on-ramp partner pulls from Venmo/PayPal balance	Non-crypto US users
Bank Transfer (ACH/SEPA)	Direct bank → on-ramp → crypto in receiver wallet	Larger amounts, low fees

Why phone-native wins over desktop checkout.

Desktop checkout is dying. Every payment surface lives in your pocket. This is the opportunity cost of any non-mobile flow:

Every web checkout that doesn't route through the phone is leaving conversions on the table. App Clip captures all of it natively.

08

SECTION EIGHT

Five phases, consumer-first.

○ PHASE 01 iOS App Clip (MVP)

Apple Pay + Connect Wallet as launch rails. App Clip Code generation. Single partner pilot (one crypto exchange or wallet).

→ Goal: Prove the App Clip flow converts higher than any URL alternative.

○ PHASE 02 Full Fiat Rail Suite

Venmo, PayPal, ACH bank transfer via on-ramp partners. Unlocks the non-crypto-native majority.

→ Goal: Capture mainstream senders who don't own crypto.

○ PHASE 03 CEX Connectors + Any-Token-Any-Chain

Coinbase, Binance, Kraken APIs. Universal swap routing via DEX aggregators (1inch, LiFi, Squid).

→ Goal: Capture funds-on-exchange majority and scattered-holdings power users.

○ PHASE 04 Full Native App + Android Parity

App Clip graduates to full app for power users. Address book, transaction history. Android Instant App parity.

→ Goal: Lock in power users; extend ecosystem to Android.

○ PHASE 05 White-label SDK / B2B

Sell to wallets, web apps, exchanges. Anyone can mint an App Clip Code that lands in our portal.

→ Goal: Become payment infrastructure.

Consumer-first, not B2B-first.

WHY NOT WHITE-LABEL FIRST

- Partnerships move slowly and require proof
- B2B sales need a working product
- White-labeling without PMF ships a broken thing everywhere

WHY CONSUMER FIRST

- Real usage = real feedback = real product
- Traction attracts partners (they come to you)
- Pivot to B2B later; can't pivot backwards to PMF

ONE-LINE PITCH

*A native iOS **App Clip** that lets anyone send any payment method to any crypto wallet — no install, no browser, no friction.*

THE PROMISE

Scan.
Pay.
Done.
